## Setting

For each of n independent subjects, suppose two continuous outcomes are potentially observed. Let  $T_i$  denote the target outcome, and let  $S_i$  denote the surrogate outcome. Group the target and surrogate outcomes into a bivariate outcome vector  $Y_i = (T_i, S_i)'$ . For each subject, either the target or the surrogate is potentially missing. Suppose the target mean depends on a vector of covariates  $x_i$ , and the surrogate mean depends on a vector of covariates  $z_i$ :

$$\mu_{T,i} = \mathbb{E}(T_i|x_i) = x_i'\beta$$
  
$$\mu_{S,i} = \mathbb{E}(S_i|z_i) = z_i'\alpha$$

Let  $\mu_i = (\mu_{T,i}, \mu_{S,i})'$  denote the mean vector. Consider the bivariate normal regression model:

$$\binom{T_i}{S_i} \Big| (x_i, z_i) \sim N \left\{ \binom{x_i'\beta}{z_i'\alpha}, \begin{pmatrix} \Sigma_{TT} & \Sigma_{TS} \\ \Sigma_{ST} & \Sigma_{SS} \end{pmatrix} \right\}$$

This package provides methods for estimation of the model parameters  $(\beta, \alpha, \Sigma)$ , and for inference on components of the target regression parameters  $\beta$ . In the case of bilateral (target, surrogate) missingness, estimation is performed via an expectation maximization (EM) procedure. In the case of unilateral target missingness, estimation is performed via an accelerated, generalized least squares (GLS) procedure.

## Example Data

Below, data are simulated for  $n=10^3$  subjects. The target X and surrogate Z design matrices each contain an intercept and three standard normal covariates. The regression coefficient for the target outcome is  $\beta=(-1,0.1,-0.1,0)$ . The regression coefficient for the surrogate outcome is  $\alpha=(1,-0.1,0.1,0)$ . The target and surrogate outcome each have unit variance  $\Sigma_{TT}=\Sigma_{SS}=1$ . The target-surrogate covariance, equivalently the correlation, is  $\Sigma_{TS}=\Sigma_{ST}=0.5$ . An outcome matrix for which 10% of the target outcomes and 20% of the surrogate outcomes are missing completely at random is simulated using rBNR.

```
library(SurrogateRegression)
set.seed(100)
# Observations.
n < -1e3
# Target design.
X \leftarrow cbind(1, matrix(rnorm(3 * n), nrow = n))
# Surrogate design.
Z \leftarrow cbind(1, matrix(rnorm(3 * n), nrow = n))
# Target parameter.
b \leftarrow c(-1, 0.1, -0.1, 0)
# Surrogate parameter.
a \leftarrow c(1, -0.1, 0.1, 0)
# Covariance matrix.
sigma \leftarrow matrix(c(1, 0.5, 0.5, 1), nrow = 2)
# Generate data.
Y \leftarrow rBNR(X, Z, b, a, t_miss = 0.1, s_miss = 0.2, sigma = sigma);
t <- Y[, 1]
s <- Y[, 2]
```

## Formatting Assumptions

The target and surrogate outcome vectors (t, s) both have length n. The unobserved values of the target or surrogate outcome are set to NA. The target X and surrogate Z model matrices are numeric, with all factors and interactions expanded. The model matrices contain no missing values.

### Estimation

Estimation of the bivariate normal regression model is performed using Fit.BNR. If the surrogate outcome vector s contains missing values, or if the surrogate design matrix Z differs from the target design matrix X, then the EM algorithm is applied. Otherwise, estimation is performed via GLS, which is significantly faster.

```
# Fit bivariate normal regression model.
fit <- Fit.BNR(
    t = t,
    s = s,
    X = X,
    Z = Z
)
show(fit)

#### Inference

Wald and Score tests on  $\beta$  are specified using a logical vector is\_zero, with length equal to the number of columns in the target model matrix X, and indicating which regression coefficients are zero under the *null hypothesis*. At least one element of is\_zero must be TRUE (i.e. a test must be specified) and at least one element of is zero must be FALSE (i.e. a null model must be estimable).

Below, various hypotheses are tested on the example data. The first is an overall test of  $H_0: \beta_1 = \beta_2 = \beta_3 = 0$ , which is false. The second assesses  $H_0: \beta_1 = \beta_2 = 0$ , which is again false, leaving  $\beta_3$  unconstrained. The final considers  $H_0: \beta_3 = 0$ , which is true, leaving  $\beta_1$  and  $\beta_2$  unconstrained. All models include an intercept  $\beta_0$  under the null.

```
cat("Joint score test of b1 = b2 = b3 = 0","\n")
test_spec <- c(FALSE, TRUE, TRUE, TRUE)
signif(Test.BNR(t, s, X, Z, is_zero = test_spec, report = FALSE, test = "Wald"), digits = 2)
signif(Test.BNR(t, s, X, Z, is_zero = test_spec, report = FALSE, test = "Score"), digits = 2)
cat("\n","Joint score test of b1 = b2 = 0, treating b3 as a nuisance","\n")
test_spec <- c(FALSE, TRUE, TRUE, FALSE)
signif(Test.BNR(t, s, X, Z, is_zero = test_spec, report = FALSE, test = "Wald"), digits = 2)</pre>
```
